### **Objectives**

- This lesson covers the following objectives:
  - Write a single-dimensional array in a Java program using primitive data types
  - Write a single-dimensional array in a Java program using reference (Object) types
  - Write a 2-dimensional array in a Java program using primitive data types
  - Write a 2-dimensional array in a Java program using reference (Object) types
  - Declare an array, initialize an array, and traverse the array

ORACLE Academy

JF 6-1

### Overview

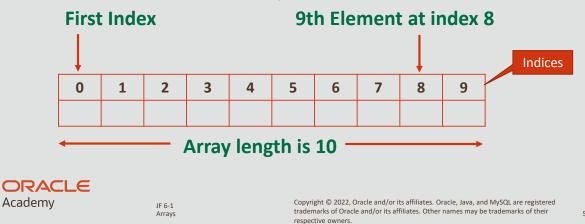

- This lesson covers the following topics:
  - -Describe array initialization
  - Distinguish between the String method length() and an array's length value
  - Rewrite a Java program to store integers into an array,
     perform a mathematical calculation, and display the result
  - -Use alternative array declaration syntax

JF 6-1

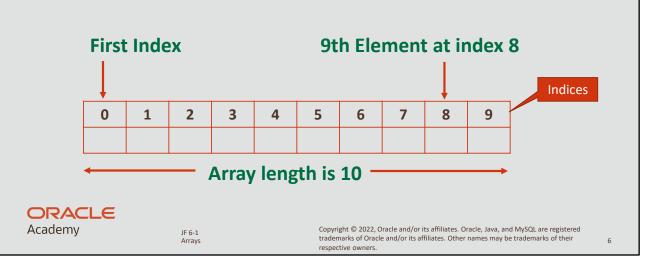

### What is an Array?

- An array is a collection of values of the same data type stored in a container object
- Can be any number of values
- Length of the array is set when the array is declared
- Size is fixed once the array is declared

### **Array Elements**

- Every value is called an element
- Each element is accessed by an index
- Index must be an integer
- Index always starts at 0

### **Array Data Types**

- Arrays may contain any data type, such as:
  - -Primitive
  - -Pre-defined objects, such as Strings from the Java API
  - Programmer-Defined objects, such as instances of a class that you create

JF 6-1

## Declaring an Array

- There are three parts to declaring an array:
  - -Data type
  - -Variable name
  - -Array size

JF 6-1

# Declaring an Array Examples

- An array declaration can be done in one or two lines
- Both examples below are equivalent array declarations

```
data_type[] variable_name;
variable_name = new data_type[size];
//declare an array using two lines of code
```

```
data_type[] variable_name = new data_type[size];
//declare an array using one line of code
```

### Declaring an Array Example

- A friend brings you a bouquet of six different flowers
- You want to write a program to store each type of flower in the bouquet
- The code segments below are identical ways to declare an array of Strings called myBouquet
- The size is set to six elements so it may store each type of flower in your bouquet

```
String[] myBouquet;
myBouquet = new String[6];
```

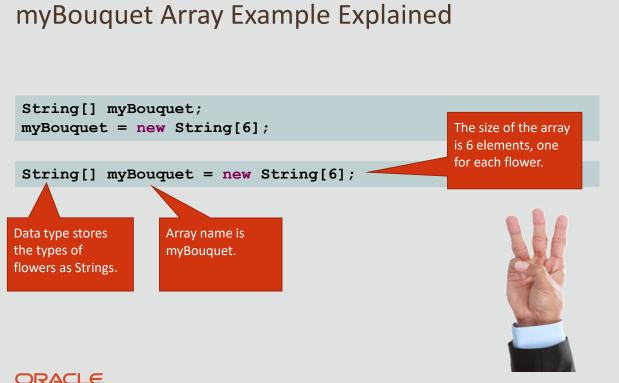

String[] myBouquet = new String[6];

### Identify Components of an Array Declaration

 Identify the three components of an array declaration for each of these arrays of primitive data types

```
1. int[] myArray;
myArray = new int[20];
```

- 2. char[] sentence = new char[100];
- 3. double[] teamPoints = new double[5];

	Data Type	Name	Size

### Alternative Array Declaration Syntax

- An alternative way to declare arrays is to place the brackets used to declare an array on either side of the array identifier
- Syntax introduced:

```
int[] primeNumbers;
int[] evenNumbers;
double[][] prices;
String[] words;
Point[] coordinates;
Rectangle[][] blocks;
```

### Alternate syntax:

```
int primeNumbers[];
int evenNumbers[];
double prices[][];
String words[];
Point coordinates[];
Rectangle blocks[][];
```

Academy

13

The alternate syntax is rarely used by Java programmers.

### **Alternative Array Declaration Syntax**

- Either declaration will work
  - The Alternate Syntax is similar to that used in the language of C
  - The syntax used to introduce arrays actually reads much clearer
  - -The first line would read "Integer array primeNumbers."
- Syntax introduced:

```
Alternate syntax:
```

```
int[] primeNumbers;
int[] evenNumbers;
double[][] prices;
String[] words;
Point[] coordinates;
Rectangle[][] blocks;
```

```
int primeNumbers[];
int evenNumbers[];
double prices[][];
String words[];
Point coordinates[];
Rectangle blocks[][];
```

### Initializing an Array

- Once you declare an array, you must initialize it to set the values for specified indexes
- There are three components to initializing an array:
  - -Variable name
  - -Index
  - -Value

### Ways to Initialize an Array

- An array can be initialized in two different ways:
  - -Declare the array, then initialize each element
  - -Have declaration and initialization occur in the same step
- Example of declaring and initializing in two steps:

```
data_type[] variable_name = new data_type[size];
variable_name[index] = value; //repeat for each index
```

Example of declaring and initializing in one step:

```
data_type[] variable_name = {val1, val2, ...};
```

### Initializing an Array Example 1

- Recall the declaration of the String array myBouquet
- Once the array is declared, the code below initializes the elements and stores the flower types
- The index of an array begins at 0, so the first element will be added to index 0

# Initialize an Array Example 1

• The array of flower types will look like this:

Index:	0	1	2	3	4	5
Value:	Rose	Sunflower	Daisy	Dandelion	Violet	Lily

ORACLE Academy

JF 6-1 Arrays Copyright © 2022, Oracle and/or its affiliates. Oracle, Java, and MySQL are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

### Initialize an Array Example 2

 The array myBouquet could also be declared and initialized using the second notation as follows:

 Notice that using this method does not specify size, but it is assigned a size based on the number of elements in the list between the {}

JF 6-1

19

Often, each element is placed on a line by itself so that the code is more obvious.

### First Notation versus Second Notation

- It seems that the second notation is much shorter and easier to code
- Why would you need the first notation?

JF 6-1

### A SIMILITY SIME

### First Notation versus Second Notation

- Consider taking in five numbers from a user and storing them in an array called myArray
- You would need to declare the array, then initialize the elements one at a time as the user enters each number

#### ORACLE

Academy

JF 6-1

Copyright © 2022, Oracle and/or its affiliates. Oracle, Java, and MySQL are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

### First Notation versus Second Notation

 The second notation may be an easier way to initialize the array if you already know the contents of the array when declaring it

```
int[] myArray = {7, 24, 352, 2, 37};
```

JF 6-1

### **Array Representation**

- When arrays are declared but not yet initialized, the elements are given the default value associated with the data type
- For example, the default for numeric data types, such as int, is 0
- The default for Object types, such as String is "" (null)
- When the array is declared, the representation in the table is as follows

int[] myArray = new int[5];

Index:	0	1	2	3	4
Value:	0	0	0	0	0

JF 6-1

Copyright © 2022, Oracle and/or its affiliates. Oracle, Java, and MySQL are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

### **Updated Array Representation**

- Once you begin to initialize elements, the array is updated
- The new representation in the table is as follows

```
myArray[0] = 32;
myArray[3] = 27;
```

Index:	0	1	2	3	4
Value:	32	0	0	27	0

### **Arrays Object Types**

- Arrays are not restricted to storing primitive data types
- They can store any object type, including types you define
- For example, if a Flower class existed:
  - The flowers could be stored in the array rather than storing the flower type as a String
  - Since we know what flowers to include, the second notation can be used to initialize myBouquet of six Flowers

### **Accessing Array Length**

- With each declaration of an array, you must define a size, or length, of the array
- The length is stored as an instance variable for that object and can be accessed using the arrayName.length notation
- This technique is useful in the following example:
  - -Establish an array with a size based on the user input
  - Enter a segment of code where the user's input is no longer in scope
  - You would need to access the instance variable length for that array
  - -In short, arr.length returns the length of the array, arr

26

With Strings, there was a length() method. With arrays, it is just length without the ().

### Iterate Through an Array

- To iterate through, or traverse, an array means to progress through each element of the array by index number
- Iterating through an array is useful when:
  - -You wish to access each element of an array in order
  - You wish to initialize the elements of an array as all the same value
- Use .length when iterating rather than the integer value entered when declaring the array
- This will assure that you do not receive an index out of bounds error

ORACLE

Academy JF 6-1

Copyright © 2022, Oracle and/or its affiliates. Oracle, Java, and MySQL are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

27

You could also iterate through an array and initialize each element to a different value. You could prompt the user for the values or you could read them from a file.

### Iterate Through an Array Example

- To initialize an array of integers called allTwos, so that each element is 2, use a for loop as shown below
- The first line of code is the array declaration
- It declares an array called allTwos with a size of 10
- The for loop iterates through the indexes and for each index in the array, the value at that index is set to 2

```
int[] allTwos = new int[10];
for(int index = 0; index < allTwos.length; index++) {
    allTwos[index] = 2;
}//end for
    Note how the length of the array is</pre>
```

accessed to keep from going out of bounds for the array's index.

### When Iteration is Helpful

 In the flower example, iteration helps if you wish to print out the flower types stored in the myBouquet array

- Use a for loop to iterate through this array
- The initialized counter within the for loop can be used for incrementing through the indexes, as shown below
- What displays as a result of this code?

```
//remember that the index range is 0 to 5 for an array of size 6
for(int index = 0; index < myBouquet.length; index++) {
         System.out.println(myBouquet[index]);</pre>
```

### for-each Loop

- Java offers a for-each loop, an alternative to using the initialized counter to iterate through an array
  - When used to access the elements of an array, the for- each loop works the same way as the for loop, but is implemented in a simpler way
  - -If we replace the for loop code from our previous example with the following code, we get the same result

```
//remember that the index range is 0 to 5 for an array //of size 6
for (String myFlower : myBouquet)
{
    System.out.println(myFlower);
}//end for

CRACLE
Academy

JF 6-1
Arrays

```

The for-each loop has a simpler syntax than the for loop for iterating through an array but it does not have a loop control variable. Thus, if you wanted, for example, to print each element with the element number before it, the for-each loop would not be the best choice.

### for-each Loop

- The for-each loop accesses and (one-at-a-time) returns all elements of an array
  - Changes to the array elements cannot be made using a for each loop
  - If we replace the for loop code from our previous example with the following code, we get the same result
  - The example below will print the length of each string in the array myBouquet

```
//remember that the index range is 0 to 5 for an array //of size 6
for (String myFlower : myBouquet)
{
    System.out.println(myFlower);
}//end for
```

### What We Know About Arrays

- What we know about arrays:
  - Arrays are an object type that can store any primitive or object type
  - -Therefore, arrays can store arrays
  - The concept of storing an array of arrays is called a twodimensional array

JF 6-1

### Two-Dimensional Arrays

- A two-dimensional array, called an "array of arrays," is an array that stores other arrays
- The number of arrays contained within the array is defined upon declaration
- The number of items in each internal array is also defined upon declaration

JF 6-1

34

There is no limit in Java to how many dimensions an array may have. The limitation is the amount of memory the computer has to store the array elements (and your sanity).

### Two-Dimensional Array Example

- This example shows an array of two arrays with three elements in each array
- A two-dimensional array can be visualized as a table with rows and columns
- The example below has two rows and three columns

```
int[][] nums = { {14,51,16}, {12,73,87} };
```

JF 6-1

### Declaring a Two-Dimensional Array

- Components of two-dimensional arrays:
  - -Data type
  - -Variable name
  - -Array size
- To declare a two-dimensional array, use either of the syntax examples below

```
data_type[][] variable_name;
variable_name = new data_type[size1][size2];
//declare it using two lines of code
```

```
data_type[][] variable_name = new data_type[size1][size2];
//declare it using one line of code
```

# Declaring a Two-Dimensional Array Example 1

```
int[][] myArray;

#### Declaring a Two-Dimensional Array Example 1

- When declaring a two-dimensional array:
  - The number in the first set of brackets [2] is the number of arrays the container holds (rows)
  - -The number in the second set of brackets [3] is the number of elements in each of those arrays (columns)
- Another way to declare myArray may look like this:

```
int[][] myArray = { {0,0,0}, {0,0,0} };
```

# Declaring a Two-Dimensional Array Example 2

- Your friend brought you three of each type of flower, and each of the three flowers are different colors
- A single-dimensional array makes it tedious to keep track of this data
- A two-dimensional array allows you to store six arrays, one for each flower type, and have each array store the colors of each of the three flowers
- The following code declares an array that holds six arrays, each of length three:

```
String[][] myBouquet = new String[6][3];
```

#### Initializing a Two-Dimensional Array

- Two-dimensional arrays, just like single-dimension arrays, can be initialized using two different methods
- Method 1:
  - -i is the index of the internal array (row) and j is the index of the element within that array (column) that is being initialized

```
public class TwoDTester{
   public static void main(String[] args) {
      Scanner in = new Scanner(System.in);
      int[][] nums = new int[3][2];
      for(int i = 0; i < nums.length; i++) {</pre>
         for(int j = 0; j < nums[i].length; j++){</pre>
           System.out.println("Enter a value for row " + i + ", column " + j);
           nums[i][j] = in.nextInt();
         }//end for
      }//end for
   }//end main
 }//end class TwoDTester

                                                  respective owners.
```

A loop inside of another loop is known as nesting. There is no limit in Java to how many levels deep loops can be nested.

## Initializing a Two-Dimensional Array

- Method 2: Declares and initializes all arrays and all elements within those arrays in the same line of code
- However, you must know the values that you want the array to contain to initialize the array at the same time that it is declared

```
public class TwoDTester2{
   public static void main(String[] args){
      int[][] nums = {{2,3,7},{15, 98, 2}};
   }//end main
}//end class TwoDTester2

#### Using Second Notation to Initialize the Array

- Since we already know the content of the arrays for our bouquet, use the second notation to initialize the array

## Visualizing a Two-Dimensional Array

- Lining up the values during initialization helps to keep track of how data is organized in a two-dimensional array
- In the code examples below, notice how the second form is easier to visualize

This is a great example of why each row should be on a line by itself. As first written, it is not easy to immediately see what is going on.

# Accessing Data in a Two-Dimensional Array

## Accessing the Length of Two-Dimensional Arrays

- Length is an instance variable defined by the size of each declared array
- Two-dimensional arrays have two different lengths:
  - Length of the outer array
  - -Length of the internal arrays

Length of the outer array is the same as how many rows. Length of the internal arrays is the same as how many columns.

# Length of Outer and Inner Arrays

 The length of the outer array, which is the length that describes the number of arrays contained (rows), is accessed like a typical array

```
int numArrays = arrayName.length;
```

- The length of the internal arrays, which is the length that describes the number of elements each array contains (columns), is accessed using the following notation
- Brackets [] tell the program that it is accessing the length of the internal arrays, and row says which array

int numElementsInEach = arrayName[row].length;

```

- Which of the following is not true?
- Can you identify which one has improper syntax for accessing the length?

```

# Placing Students in the Two-Dimensional Array

- You already know how to:
  - -Iterate through the array using a for loop
  - -Create a new student for each name inside loop
  - Place the students in the two-dimensional array using a nested for loop

#### **Nested for Loops**

- A nested for loop:
  - -Is a for loop inside a for loop
  - Is can be used to iterate through two-dimensional arrays using the outer for loop counter as the index for the arrays (rows) and the inner for loop counter as the index for the elements of each array (columns)
- Consider the following two-dimensional array declaration:

```
Student[][] groups = new Student[3][5];
```

## **Nested for Loops**

• To iterate through the array and initialize each student as "Temp", use nested for loops as shown below

```
//i keeps track of the rows
for(int i = 0; i < groups.length; i++) {
    //j keeps track of the columns
    for(int j = 0; j < groups[i].length; j++) {
        groups[i][j] = new Student("Temp");
    }//end for
}//end for</pre>
```

# Complete Tasks Using Nested for Loops

- How could we complete all three tasks?
  - -Iterate through the existing array
  - -Create a new student for each provided name
  - -Place each student into one of the three groups

# Complete Tasks Using Nested for Loops

```
String[] studentNames;
//Assume studentNames is initialized with 15 names

Student[][] groups = new Student[3][5];//Declare your array
  int x = 0;
  for(int i = 0; i < groups.length; i++){
    for(int j = 0; j < groups[i].length; j++){
        String name = studentNames[x];
        groups[i][j] = new Student(name);
        x++;
    }//End inner for loop
}//End outer for loop</pre>
```

For nested blocks it is good practice to put a comment after the closing brace of the nested loops (// End inner for loop) so that we can easily identify where each code block ends.

## **Command Line Arguments**

- An array has always been a part of the main method
- The String array args is always a parameter for the main method

public static void main(String[] args)

Command line arguments were used quite a bit more before GUIs became common.

# Command Line Arguments: Adding Extra Arguments

 If you run a Java program from a command line environment, you can type in extra arguments as follows:

#### java Test apples peaches pumpkin pie

- The keyword java tells the command line environment to use the JVM to run the program Test
- The array args gets populated with the Strings: apples, peaches, pumpkin, and pie
- -Using a Java IDE, we avoid the command line environment; however, we can use command line arguments in a Java IDE

#### Using Command Line Arguments in Eclipse

- Access the arguments tab for your program by going to the Run menu and choosing Open Run Dialog
- Click the Arguments tab and type in the Strings: Apples Peaches Pumpkin Pie

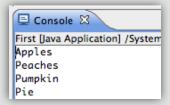

Place "double quotes" around multi-word arguments. For example, red "light blue" green. This is three arguments. Without the quotes, it would have been four arguments.

If you are using an IDE other than Eclipse, your instructor will guide you how to do this.

#### Using Command Line Arguments in Eclipse

- Click Run for the program
- All of the Strings that were typed in the Arguments tab will print to the console

```
public class TestArgs {
   public static void main(String[] args) {
      for(int i=0;i<args.length;i++) {
            System.out.println(args[i]);
      }//end for
   }//end main
}//end class TestArgs</pre>
```
